* Nitrogen fixing microbes in agriculture *

⇒ Nitrogen fixation is very important event in which atmospheric nitrogen fixed in the soil, which ultimately increase the fertility of soil.

⇒ The reduction of atmospheric gaseous nitrogen in ammonia is called N_2 -fixation.

⇒ Nitrogen is very essential nutrients of living beings, which is required for synthesis of protein/amino acid/nucleic acids, etc.

⇒ The conversion of atmospheric inorganic nitrogen into organic nitrogen in plants take place by certain micro-organisms.

By: Aniket

* kinds of N_2 -fixation:

(1) Atmospheric- N_2 -fixation: The atmospheric nitrogen contains 79% nitrogen of total gas present in atmosphere, but majority of plants cannot get atmospheric-nitrogen.

⇒ In atmospheric nitrogen, lightning temperature in the atmosphere plays very important role in which atmospheric nitrogen converted into

By: Aniket

(ii) Biological nitrogen fixation: - when micro-organisms involve in the conversion of atmospheric nitrogen into inorganic nitrogen compound by living-organisms is called Biological-N₂-fixation.

⇒ The N₂-fixation micro-organisms are found in 3 different forms:-

i) Autotrophic - Biological-N₂-fixation: - It is aerobic-micro-organisms in the form of Blue green organisms, and anaerobic micro-organisms in the form of Rhodospirillum.

By: Ariket

(ii) Heterotrophic Biological N₂-fixation: - It is found in the form of aerobic micro-organisms.

Ex:- Azotobacter and it is also found in anaerobic form e.g. Clostridium.

(iii) Symbiotic Biological N₂-fixation: - The symbiotic bacteria in the form of rhizobium helps in N₂-fixation in root nodule of legumes, which fixes atmospheric N₂ are called Amino-nitrogen nodule.

By: Ariket

(3)

↓ Aniket

⇒ The leguminous plant, where root nodules are found
i.e. Bean, Pea, Groundnut, pulses plant etc.

↓

⇒ The root nodule contain a pigment called leg. Haemoglobin, which is pink in colour, and it is closely related to Haemoglobin present in RBC.

↓

⇒ The symbiotic N_2 -fixing micro-organism is not only in leguminous plant.

↓

⇒ It also contains some non-leguminous plant in
Fungi, algae, mycorrhiza etc.

↓

⇒ The free living N_2 -fixing micro-organism like Cyanobacteria and photosynthetic bacteria fix atmospheric nitrogen.

↓

Ex:- Azolla and roots of gymnosperm.

By:- Aniket

Mechanism of Biological N_2 -fixation: The plant picks up nitrogen from the soil in the form of ammonium ions or nitrate ions.

↓

⇒ Ammonia is the main product of biological N_2 -fixation.

By:- Aniket

By: Arifet
⇒ It is converted to nitrate by number of soil bacteria.

⇓
⇒ There are different event taking place during biological N_2 fixation.

⇓
⇒ The conversion of atmospheric nitrogen into inorganic organic usable form in the presence of living being is called "Biological- N_2 -fixation".

⇓
⇒ The process of biological N_2 -fixation take's place by 2 main types of micro-organism:-

i.) free living asymptotic micro-organism

ii.) Symbiotic micro-organism

By: Arifet

1.) free living asymptotic micro-organism:- There are large number of free living bacteria and cyanobacteria which fix atmospheric nitrogen into usable form.

⇓
⇒ These micro-organism can be categories as follows:-

a.) free-living aerobic N_2 -fixing bacteria:- Ex:- Azotobacter.

b.) free-living anaerobic N_2 -fixing bacteria:- Ex:- Clostridium

c.) free living photoautotrophic N_2 fixing bacteria:- Ex:- Rhodospirillum

d.) free living chemosynthetic N_2 -fixing bacteria:- Disulphobium

By: Arifet

By: - Aniket
i) Free-living N_2 -fixing cyanobacteria: - Large no. of heterocysts of cyanobacteria or B.A.N.

ii) Symbiotic micro-organism: - Many bacteria and cyanobacteria fix atmospheric N_2 in its symbiotic association with other plants are called "Symbiotic N_2 fixation".

↓
Ex: - i) Rhizobium in association with roots of leguminous plant.

By: - Aniket
ii) Anthocyanus (Bryophytes): - In association with nostoc.

iii) Azolla (hectoterran): - In association with Anabena-Azolla.

iv) Coralloid group of cycas in association with Anabena and nostoc.

v) Mechanism of N_2 -fixation in leguminous plant: -

↓
⇒ Rhizobium is the most important N_2 fixing bacteria which fixes atmospheric N_2 in symbiotic association with root of leguminous plant (Peas, bean etc.)

↓
⇒ Initially bacteria grows in the soil near the root of higher plant where it fail to fix N_2 .

By: - Aniket

By: Aniket

6

⇒ The bacteria comes in contact with the root of leguminous plant and it interacts chemically then enters into roots through root-hair.

⇒ The entry of bacteria into root hair depends upon various chemicals which is release from root hairs.

⇒ The root-hair forming thread like structure called "infection thread".

By: Aniket

⇒ The bacteria multiply when it enters through the infection thread.

⇒ Finally bacteria reaches upto cortex, where they enters into the cell and stimulates the cell for division.

⇒ The specific cell where bacteria grows and divide rapidly forming root nodules which contain several thousand bacteria.

⇒ In the cytoplasm of nodule, cell filled with red pigment called leg. Haemoglobin which has ability to combine rapidly with O_2 that's why it is called "oxygen scavenger".
